The exact behaviour of the Reimann Zeta conjugate pair ratio function

John Martin

Sunday, July 17, 2016

Executive Summary

Graphical examination of the Reimann Zeta conjugate pair ratio function $\frac{\zeta(s)}{\zeta(1-s)}$ reveals a simple AM-FM lineshape for the real and imaginary components with (i) the FM terms present in the exact terms of the Reimann Seigal $\theta(t)$ function and $\Gamma(0.5+it)$ and (ii) only the AM term is dependent on the distance of the real value of s from 0.5. The envelope function $abs(\frac{\zeta(s)}{\zeta(1-s)})$ is smooth and increases (decreases) with increasing distance from the critical line for $Re(s) < 0.5$ ($Re(s) > 0.5$) indicating no zeroes away from the critical line in agreement with the Reimann Hypothesis.

Introduction

The Reimann Zeta function is defined (1), in the complex plane by the integral

$$\zeta(s) = \frac{\prod(-s)}{2\pi i}\int_{C_{\epsilon,\delta}} \frac{(-x)^s}{(e^x-1)x}dx \tag{1}$$

where $s \,\epsilon\, \mathbb{C}$ and $C_{\epsilon,\delta}$ is the contour about the imaginary poles.

The Reimann Zeta function has been shown to obey the functional equation (2)

$$\zeta(s) = 2^s\pi^{s-1}sin(\frac{\pi s}{2})\Gamma(1-s)\zeta(1-s) \tag{2}$$

Following directly from the form of the functional equation and the properties of the coefficients on the RHS of eqn (2) it has been shown that any zeroes off the critical line would be paired, ie. if $\zeta(s) = 0$ was true then $\zeta(1-s) = 0$.

Figure 1 displays, the well known Reimann Zeta function behaviour for the critical line (0.5+it) and an Reimann Zeta function conjugate pair example $\zeta(s)$,$\zeta(1-s)$ for (0.2+it) , (0.8-it). The blue, green and red lines indicate respectively, the Re, Im and Abs values of the Reimann Zeta function. It can be seen that there are many zeroes along the critical line, characterised by both $Re(\zeta(0.5+it)) = Im(\zeta(0.5+it)) = 0$. For the Reimann Zeta function off the critical line (shown in the bottom two graphs), there does not appear to be any zeroes (on red line) but the complicated lineshape makes it difficult to be sure that some zeroes may occur as $t \to \infty$.

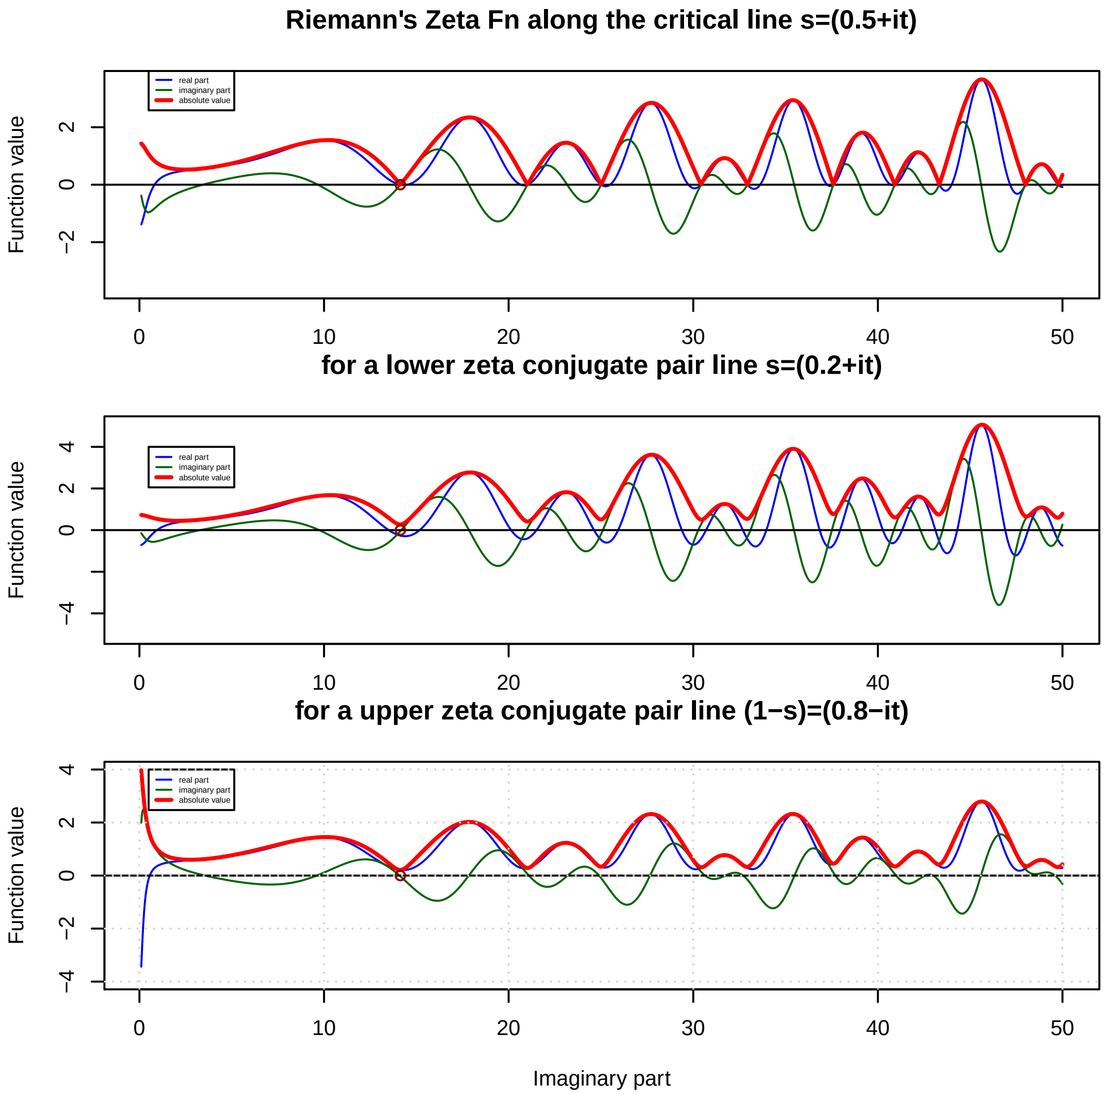

Figure 1: Reimann Zeta function behaviour

In this paper, the properties of the Reimann Zeta conjugate pair ratio function is examined. It is obtained from eqn (2) by dividing by sides by $\zeta(1-s)$.

$$\frac{\zeta(s)}{\zeta(1-s)} = 2^s \pi^{s-1} sin(\frac{\pi s}{2})\Gamma(1-s) \tag{3}$$

The validity of this estimator function depends on whether $\zeta(1-s) = 0$ off the critical line (which doesn't occur if the Riemann Hypothesis is true) and that the asymptotic behaviour of

$$\frac{lim\, \zeta(s) \rightarrow 0}{lim\, \zeta(1-s) \rightarrow 0} \tag{4}$$

is continuous. This ratio function will be shown to have a simpler lineshape than the Reimann Zeta function and has separable AM, FM components which resolves eqn (4) continuity issues.

Reimann Seigal Theta function

As a precursor to the viewing the lineshapes of $Re(\frac{\zeta(s)}{\zeta(1-s)})$ and $Im(\frac{\zeta(s)}{\zeta(1-s)})$, it is important to revisit the Reimann Seigal function and its Theta and Z components. The Reimann Seigal function is an approximating function (3) for the Reimann Zeta function along the critical line (0.5+it) of the form

$$\zeta(0.5+it) = Z(t)e^{-i\theta(t)} \tag{5}$$

where

$$\theta(t) = Im(ln(\Gamma(\frac{1}{4}+\frac{1}{2}it))) - \frac{t}{2}ln(\pi) \tag{6}$$

For values of s away from the critical line, series expansions based around the Reimann Seigal function are employed.

Figure 2, below illustrates the Reimann Seigal function for the critical line alongside the abs($\zeta(0.5+it)$). The lineshape can be understood as a combined modulation signal with a FM and AM terms both depending on t.

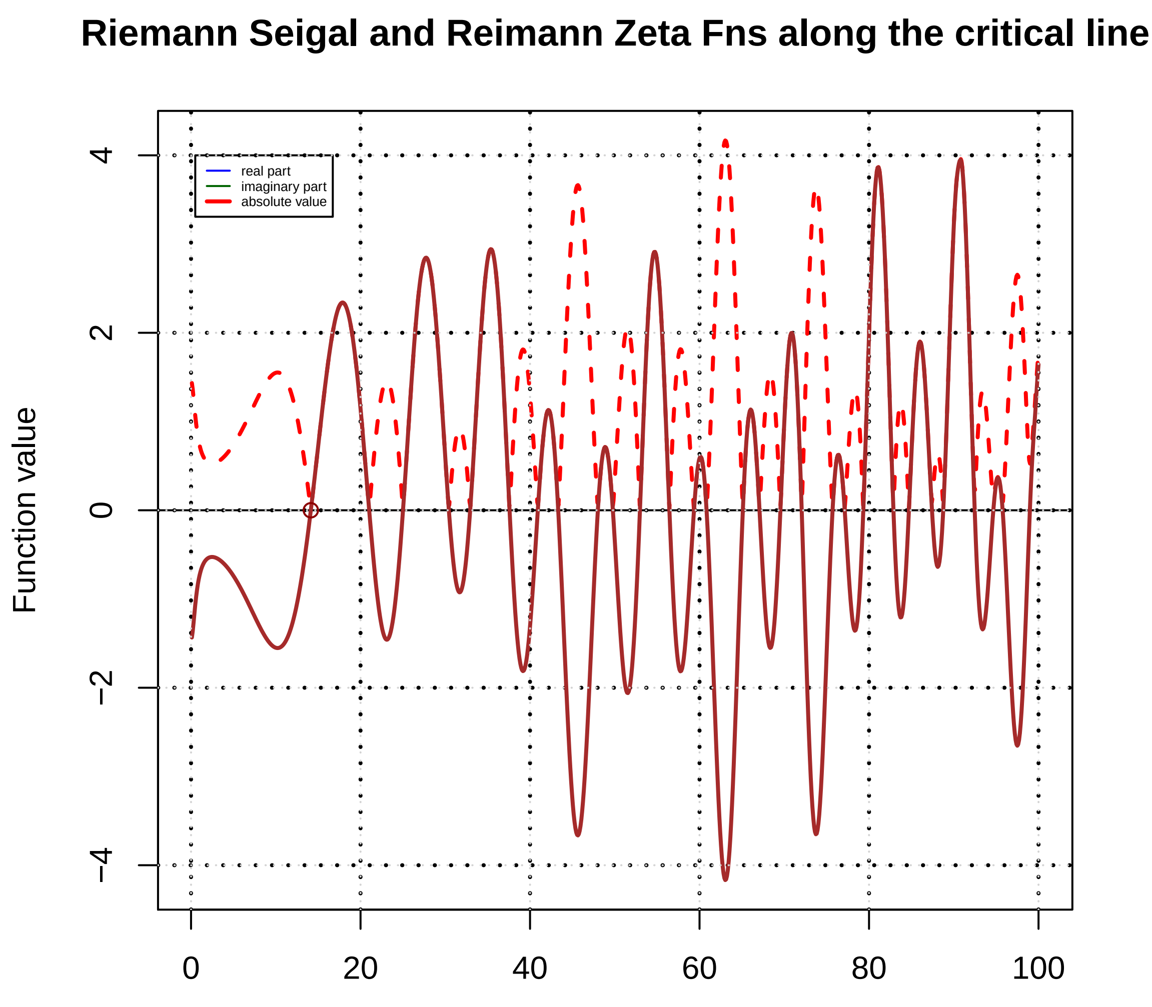

Figure 2: Reimann Seigal and Reimann Zeta function behaviour on the critical line

$\frac{\zeta(s)}{\zeta(1-s)}$ behaviour

Figure 3-5, gives the calculated $\frac{\zeta(s)}{\zeta(1-s)}$ behaviour for several lines through the critical strip, s=(0.5+it), (.4+it) and (0.1+it) respectively.

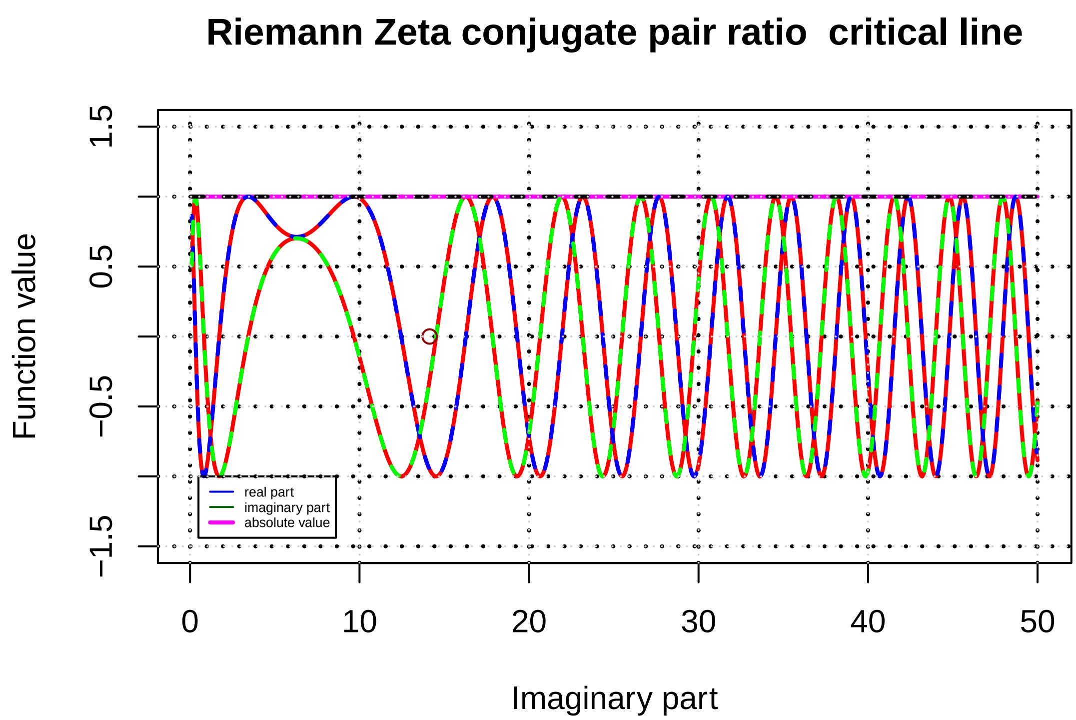

Figure 3: Reimann Zeta conjugate pair ratio function behaviour on critical line

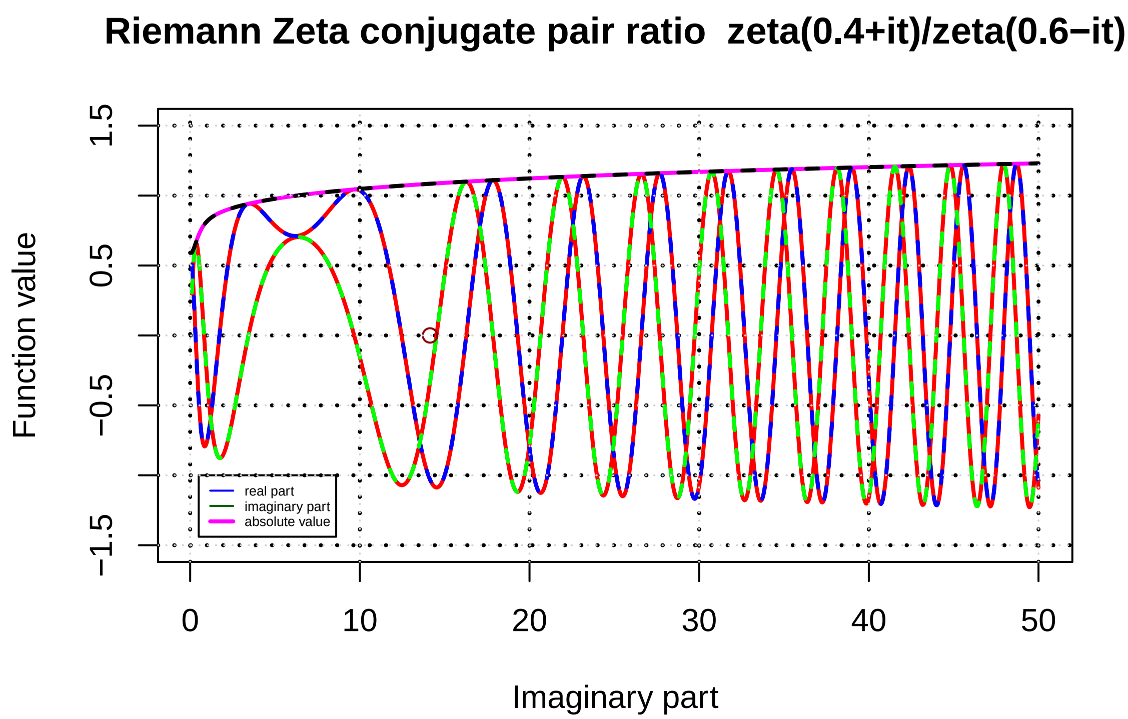

Figure 4: Reimann Zeta conjugate pair ratio function behaviour near critical line

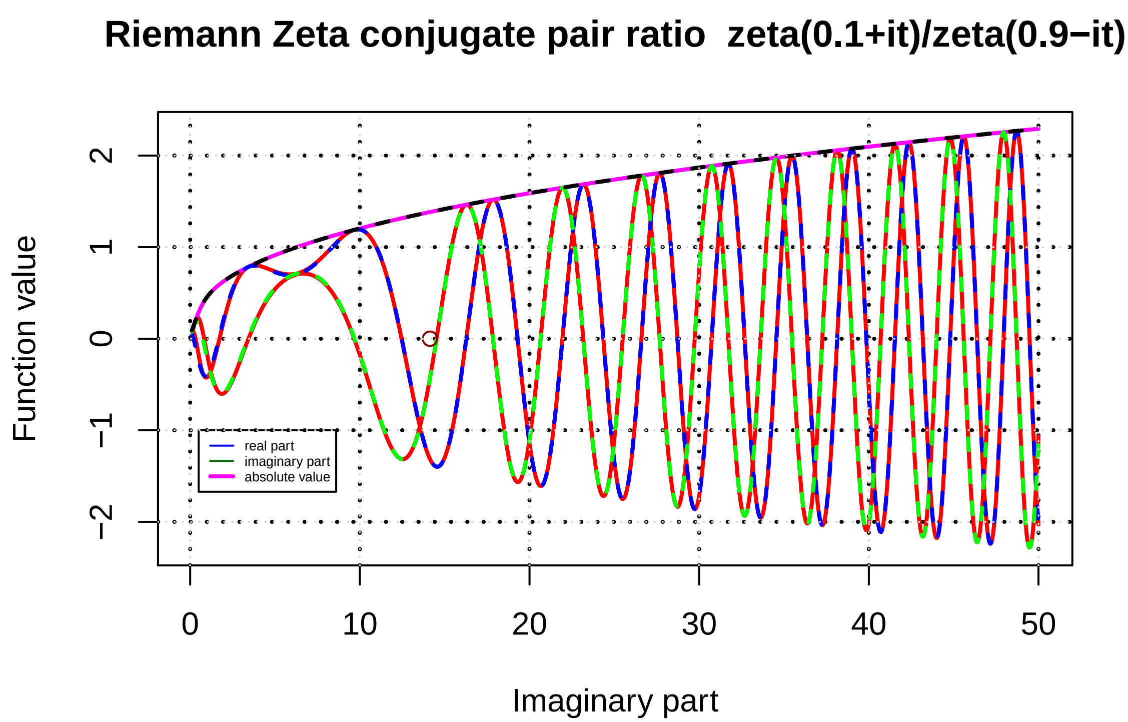

Figure 3: Reimann Zeta conjugate pair ratio function behaviour near edge of critical strip

As can be seen,

(i) the FM modulation behaviour is fixed, just a function of Im(s) = t

(ii) the AM modulation depends on t and distance from critical line abs(0.5-Re(s)). It appears to be smooth and monotonically increasing for $\frac{\zeta(a+it)}{\zeta(1-a-it)}$ where $a \leq 0.5$.

(iii) the dotted lines in figures 3-5 indicate that a fitted function has also been plotted extremely well over the numeric calculations of $\frac{\zeta(s)}{\zeta(1-s)}$. The fit agrees for a wide range of Im(s) up to Im(s) ~ 450, the limit of the "pracma" r package (4). The fitted FM modulation functional dependence was easily confirmed to be twice the Im(s) dependence of the Reimann Seigal Theta function on the critical line, but now applicable to any value of s.

$$Re(\frac{\zeta(s)}{\zeta(1-s)}) = A(Im(s), abs(0.5 - Re(s)))\dot{C}os(2 * (Im(ln(\Gamma(\frac{1}{4} + \frac{1}{2}it))) - \frac{t}{2}ln(\pi))) \tag{7}$$

$$Im(\frac{\zeta(s)}{\zeta(1-s)}) = -A(Im(s), abs(0.5 - Re(s)))\dot{S}in(2 * (Im(ln(\Gamma(\frac{1}{4} + \frac{1}{2}it))) - \frac{t}{2}ln(\pi))) \tag{8}$$

$$abs(\frac{\zeta(s)}{\zeta(1-s)}) = A(Im(s), abs(0.5 - Re(s))) \tag{9}$$

(iv) On the critical line (neglecting rounding errors), the ratio function remains smooth and continuous around the Reimann Zeta function zeroes. This behaviour occurs because the limiting behaviour of the numerator and denominator in eqn (4) are equivalent as A(Im(s),0) = 1 by the symmetry of

$$Re(0.5 + it) = Re(1 - (0.5 + it)) = 0.5 \tag{10}$$

(v) In practice, precisely on the critical line, the numeric ratio calculation broke down beyond Im(s) ~ 50. However, since the Reimann Zeta zeroes calculations accurate to 13 significant figures, were observed not to give precisely zero at t > 100 for (4) the pathology was assigned to rounding error problems. As soon as the s value was infinitesimally moved from the critical line, the numeric ratio calculation resulted in clean FM modulation

The exact functional dependence of the AM modulation function A(Im(s),abs(0.5-Re(s))) remains to be obtained but the smooth functional dependence of abs($\frac{\zeta(s)}{\zeta(1-s)}$) compared to the noisy abs($\zeta(s)$) function will allow more thorough testing. The demonstrated separable nature of the FM term, the smoothness of the abs($\frac{\zeta(0.5+it)}{\zeta(0.5-it)}$) function, excluding rounding error issues, coupled with the increasing AM signal as Re(s) differs from 0.5 gives strong evidence that no zeroes are present in the critical strip away from the critical line.

A coarse lower bound on A(Im(s),abs(0.5-Re(s))) for large Im(s), given Re(s) < 0.5 is

$$1 - log(2 * pi/Im(s)) * (.5 - Re(s)) \tag{11}$$

A coarse upper bound on A(Im(s),abs(0.5-Re(s))) for large Im(s), given Re(s) < 0.5 is

$$\frac{\Gamma(\frac{(1-s)}{2})}{\Gamma(\frac{s}{2})} \tag{12}$$

Conclusions

The Reimann Zeta conjugate pair ratio functional dependence gives a smooth natural representation of the FM contribution to the Reimann Zeta function and illustrates the Reimann Zeta function zeroes on the critical line as an interference pattern of the periodicity of the natural prime numbers. The FM modulation is determined by twice the Reimann Zeta Theta function, independent of Re(s).

The smoothness and increasing nature of the AM contribution to the Reimann Zeta conjugate pair ratio functional dependence for increasing abs(0.5-Re(s)) for Re(s) $<$ 0.5 indicates that the Reimann Hypothesis is true. Further, the separable nature of the FM modulation for the Reimann Zeta conjugate pair ratio function, ie. independent from Re(s), drives the reason for this Reimann Hypothesis behaviour.
